## About Chic

There can be little argument that Chic was disco's greatest band; and, working in a heavily producer-dominated field, they were most definitely a band. By the time Chic appeared in the late '70s, disco was already

# Why recommendation systems?

## For customer

- Narrow down the set of choices
- Discover new things
- Find things that are interesting
- Save time

# Why recommendation systems?

## For businesses

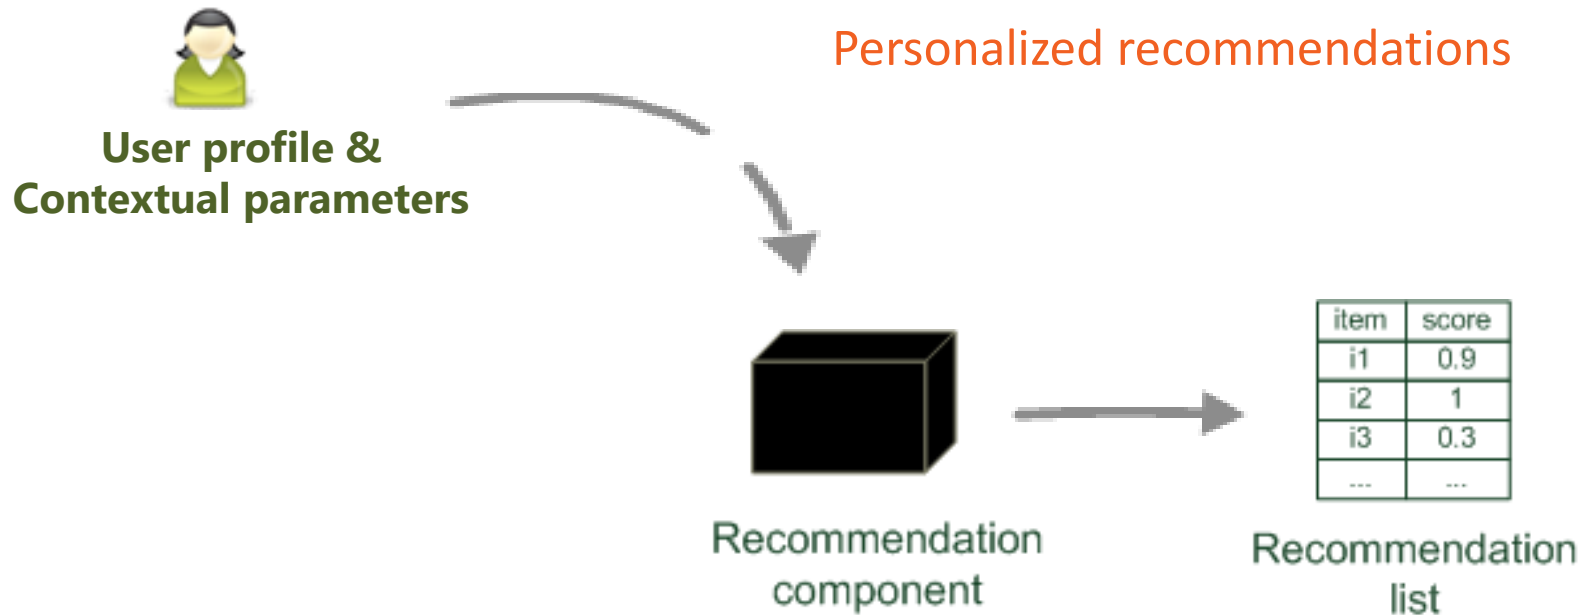

- Increase the number of items sold
- Sell more diverse items
- Increase the user satisfaction
- Better understand what the user wants

# Recommender Systems

Recommender systems reduce information overload by estimating relevance

# Recommender Systems

# Overview

- What are Recommender Systems?
- How do they work?
  - **Collaborative Recommendation**
  - Content-Based Recommendation
- How do we evaluate them?
- Example using Azure ML

# Collaborative Filtering

- Maintain a database of many users' ratings of a variety of items.
- For a given user, find other similar users whose ratings strongly correlate with the current user.
- Recommend items rated highly by these similar users, but not rated by the current user.

# Collaborative Filtering (CF)

Collaborative: "Tell me what's popular  
among those **who are like me**"

# Collaborative Filtering

- Most popular recommendation algorithm
  - Used by large, commercial e-commerce sites
  - Well-understood, variety of algorithms
  - Applicable to many domain (books, movies, songs,...)
- Approach: borrow the “wisdom of the crowd” to recommend items

# Collaborative Filtering

- Assumption:
  - Users give ratings to items
  - Users who has similar tastes in the past, have similar tastes in the future.
- User-based collaborative
- Item-based collaborative

# Collaborative Filtering

- Assumption:
  - Users give ratings to items
  - Users who has similar tastes in the past, have similar tastes in the future.
- **User-based collaborative**
- Item-based collaborative

# Movie Rating Example

Alice	5	3	4	4	?
Bob	3	1	2	3	3
Chris	4	3	4	3	5
Donna	3	3	1	5	4
Evi	1	5	5	2	1

# Movie Rating Example

**Goal:** Given Alice is an “active” user, we want to predict the rating of movie  $i$  Alice hasn’t seen before.

- Find set of users who liked the same items as Alice in the past and also had rated movie  $i$
- Predict Alice’s rating on movie  $i$
- Repeat for all items Alice has not seen and recommend the best rated.

# User-Based collaborative filtering

- How do we define similarity?
- How many neighbor should we include?
- How to generate prediction from neighbors' ratings?

# User-Based collaborative filtering

## ■ Nearest neighbors

### • Pearson correlation

$j, k$  : users

$r_{j,p}$ : rating of user  $j$  for item  $p$

$\bar{r}_j$  and  $\bar{r}_k$  are the average ratings of user  $j$  and user  $k$  over all items

$P$ : set of items, rated both by  $j$  and  $k$

Possible similarity values between -1 and 1

$$\text{sim}(j, k) = \frac{\sum_{p \in P} (r_{j,p} - \bar{r}_j)(r_{k,p} - \bar{r}_k)}{\sqrt{\sum_{p \in P} (r_{j,p} - \bar{r}_j)^2} \sqrt{\sum_{p \in P} (r_{k,p} - \bar{r}_k)^2}}$$

$j$  : Alice

$k$  : Bob

$P$ : set of items, rated by Alice and Bob

# Pearson Correlation

Alice	5	3	4	4	?	
Bob	3	1	2	3	3	sim=0.85
Chris	4	3	4	3	5	sim=0.90
Donna	3	3	1	5	4	sim=0.70
Evi	1	5	5	2	1	sim=0.79

# Pearson Correlation

# Making recommendations

- Making predictions is typically not the ultimate goal
- Usual approach
  - Rank items based on their predicted ratings
- However
  - This might lead to the inclusion of (only) niche items
- Better approach
  - Optimize according to a given rank evaluation metric

# Collaborative Filtering

- Assumption:
  - Users give ratings to items
  - Users who has similar tastes in the past, have similar tastes in the future.
- User-based collaborative
- **Item-based collaborative**

# Item-based collaborative filtering

- Basic idea:
  - Use the similarity between items (and not users) to make predictions
- Example:
  - Look for movies that are similar to movie 5
  - Take Alice's ratings for these items to predict the rating for movie 5

# Movie Rating Example

Alice	5	3	4	4	?
Bob	3	1	2	3	3
Chris	4	3	4	3	5
Donna	3	3	1	5	4
Evi	1	5	5	2	1

# Item-based Similarity Measurements

- cosine similarity

$$\text{sim}(\vec{a}, \vec{b}) = \frac{\vec{a} \cdot \vec{b}}{|\vec{a}| * |\vec{b}|}$$

- Adjusted cosine similarity

$$\text{sim}(\vec{a}, \vec{b}) = \frac{\sum_{u \in U} (r_{u,a} - \bar{r}_u)(r_{u,b} - \bar{r}_u)}{\sqrt{\sum_{u \in U} (r_{u,a} - \bar{r}_u)^2} \sqrt{\sum_{u \in U} (r_{u,b} - \bar{r}_u)^2}}$$

# Collaborative Filtering Pros

- well-understood and proven
- works well in many domains
- no knowledge engineering required
- serendipity of results

# Collaborative Filtering Cons

**Data sparsity:** New user needs to indicate preferences for sufficient number of items before getting recommendations

**Scalability:** Millions of customers ( $M$ ) and millions of items ( $N$ ).

**Grey Sheep and Black Sheep:** Grey sheep are users with inconsistent recommendations. Black sheep are the users with idiosyncratic preferences.

# Collaborative Filtering Cons

**Shilling:** Intentional manipulation of ratings of your own products and competitors products

**Diversity and Long Tail:** Rich get richer.

**Cold Start:** Need initial customer/rating database

# Content-based recommendation

Recommend items that are “similar” to the user preferences

What do we need:

- Item Profiles: content of the items
- User profiles: preferences of the user.
  - User specified or based on item ratings

# Item Profile Strategies

## ▪ **Expert Labeling**

- Assign keywords based on content
- Good for songs, movies, etc
- May be provided by creators/distributors
- Crowd sourcing?

# Content-based recommendation

## ▪ Information Retrieval (IR)

- Used for text documents (web pages, books, tweets)
- Based on word content of document set
- No expert knowledge involved
- Can be keyword or full dictionary based

# Content-based recommendation

## ■ Prediction: Simple approach

- Compute the similarity of an item and user profile based on keyword overlap

- $$\text{sim}(b_i, b_j) = \frac{2 * |\text{keywords}(b_i) \cap \text{keywords}(b_j)|}{|\text{keywords}(b_i)| + |\text{keywords}(b_j)|}$$

# Simple approach: drawbacks

- Not every word has similar importance
- Longer documents have a higher chance to have an overlap with the user profile
- Automated extraction particularly problematic

# TF-IDF

- Common Solution: TF-IDF
  - **Term Frequency:** Measures, how often a term appears (density in a document)
    - Assuming that important terms appear more often
    - Normalization has to be done in order to take document length into account
  - **Inverse Document Frequency:** Aims to reduce the weight of terms that appear in all documents

# Term Frequency

- **Term frequency (TF)**

- Let  $freq(t,d)$  number of occurrences of keyword  $t$  in document  $d$
- Let  $\max\{freq(w,d)\}$  denote the highest number of occurrences of another keyword of  $d$
- $TF(t, d) = \frac{freq(t,d)}{\max\{freq(w,d):w \in d\}}$

# Inverse Document Frequency

- **Inverse Document Frequency (IDF)**

- N: number of all recommendable documents
- $n(t)$ : number of documents in which keyword  $t$  appears
- $IDF(t) = \log \frac{N}{n(t)}$

# TF-IDF

- Compute the overall importance of keywords
  - Given a keyword  $t$  and a document  $d$

$$TF-IDF(t,d) = TF(t,d) * IDF(t)$$

# TF-IDF Exercise

- <http://lsirwww.epfl.ch/courses/dis/2006ws/exercises/IR/Exercise8.htm>
- <http://lsirwww.epfl.ch/courses/dis/2006ws/exercises/IR/Exercise%208%20solution%202007.pdf>

# Recommending items

- Simple method: nearest neighbors
  - Given a set of documents  $D$  already rated by the user (like/dislike, ratings)
    - Find the  $n$  nearest neighbors of a not-yet-seen item  $i$  in  $D$
    - Take these ratings to predict a rating/vote for  $i$

# Recommending items

- Query-based retrieval: Rocchio's method
- Probabilistic methods
- linear classification/regression algorithms
- etc

# Content-based recommenders

## Advantages

- No community required: Only need the items and a single user profile for recommendation.
- Transparency: CB models can tell you why they recommend an item, not subject to vagaries of human taste
- No cold start: new items can be suggested before being rated by a substantial number of users.

# Content-based recommenders

## Disadvantages

- Limited content analysis: requires well annotated content for good recommendations.
- Over-specialization
- New users: limited user information results in bad recommendations.

# Overview

- What are Recommender Systems?
- How do they work?
  - Collaborative Recommendation
  - Content-Based Recommendation
- **How do we evaluate them?**
- Example using Azure ML

# Evaluating Recommendation

- Metrics measure error rate
  - **Mean Absolute Error (MAE)** computes the deviation between predicted ratings and actual ratings

$$MAE = \frac{1}{n} \sum_{i=1}^n |p_i - r_i|$$

- **Root Mean Square Error (RMSE)** is similar to *MAE*, but places more emphasis on larger deviation

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^n (p_i - r_i)^2}$$

# Metrics

- Order matters, not exact ranking value
- Discounted cumulative gain (DCG)
  - Logarithmic reduction factor

$$DCG_{pos} = rel_1 + \sum_{i=2}^{pos} \frac{rel_i}{\log_2 i}$$

Where:

- *pos* denotes the position up to which relevance is accumulated
- *rel<sub>i</sub>* returns the relevance of recommendation at position *i*

# Metrics

- **Ideal discounted cumulative gain (IDCG)**

- Assumption that items are ordered by decreasing relevance

$$IDCG_{pos} = rel_1 + \sum_{i=2}^{|h|-1} \frac{rel_i}{\log_2 i}$$

- **Normalized discounted cumulative gain (nDCG)**

$$nDCG_{pos} = \frac{DCG_{pos}}{IDCG_{pos}}$$

- Normalized to the interval [0..1]
