Ensemble Methods And Random Forests

Ensemble Methods

- Overview and rationale
- Binomial Distribution
- Bagging
 - Random Forests
- Boosting
 - AdaBoost

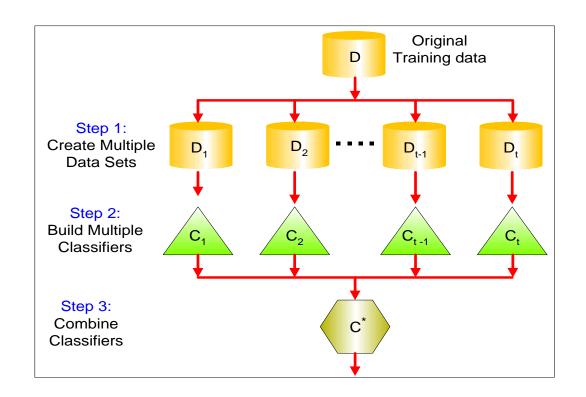

Ensemble Methods

- Improve classification accuracy by combining classifiers
- You can also have an ensemble of regression models

General Idea of Ensemble Methods

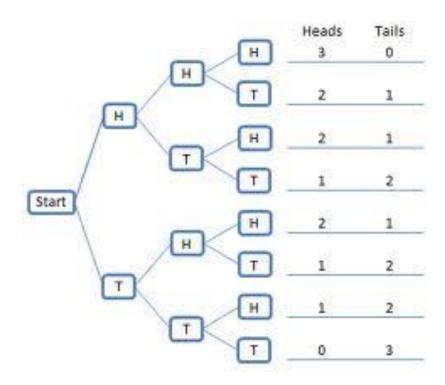

Ensemble Methods

- Boosting
- AdaBoost

Binomial Distribution

Binomial Distribution

$$f(k; n, p) = \Pr(X = k) = \binom{n}{k} p^k (1 - p)^{n-k}$$

Tossing A Biased Coin

What is the probability of 0,1,2,3,4,5,6 heads in six tosses of a biased coin?

$$n = 6$$

 $k = 0,1,2,3,4,5,6$
 $P=0.3$ (prob of head)

$$\begin{split} &\Pr(0 \text{ heads}) = f(0) = \Pr(X=0) = \binom{6}{0} 0.3^0 (1-0.3)^{6-0} \approx 0.1176 \\ &\Pr(1 \text{ head }) = f(1) = \Pr(X=1) = \binom{6}{1} 0.3^1 (1-0.3)^{6-1} \approx 0.3025 \\ &\Pr(2 \text{ heads}) = f(2) = \Pr(X=2) = \binom{6}{2} 0.3^2 (1-0.3)^{6-2} \approx 0.3241 \\ &\Pr(3 \text{ heads}) = f(3) = \Pr(X=3) = \binom{6}{3} 0.3^3 (1-0.3)^{6-3} \approx 0.1852 \\ &\Pr(4 \text{ heads}) = f(4) = \Pr(X=4) = \binom{6}{4} 0.3^4 (1-0.3)^{6-4} \approx 0.0595 \\ &\Pr(5 \text{ heads}) = f(5) = \Pr(X=5) = \binom{6}{5} 0.3^5 (1-0.3)^{6-5} \approx 0.0102 \\ &\Pr(6 \text{ heads}) = f(6) = \Pr(X=6) = \binom{6}{6} 0.3^6 (1-0.3)^{6-6} \approx 0.0007 \end{split}$$

Rolling a Die

- When rolling a die 100 times, what is the probability of rolling a "4" exactly 25 times?
- Number of trials n = 100
- Number of successes k = 25
- Probability of a '4' in a single roll = 1/6

$$\binom{100}{25} \left(\frac{1}{6}\right)^{25} \left(1 - \left(\frac{1}{6}\right)\right)^{100 - 25}$$

R functions: dbinom(25,size=100,prob=1/6) = 0.009825882 Pbinom is for calculating cdfs

Multiple Choice Test

- A test consists of 10 multiple choice questions with five choices for each question. As an experiment, you guess on each and every answer without even reading the questions.
 - What is the probability of getting exactly 6 questions correct on this test?
 - What is the probability of getting at least 6 questions correct on this test?
 - What is the probability of getting **less than 6** questions correct on this test?
 - What is the probability of getting all 10 questions correct on this test?

Applications

- Number of life insurance holders who will claim in a given period
- Number of loan holders who will default in a certain period
- Number of false starts of a car in n attempts
- Number of faulty items in n samples from a production line
- AND Ensemble Methods

Why Does It Work?

- Suppose there are 25 base classifiers
 - Each classifier has error rate, $\varepsilon = 0.35$
 - Assume classifiers are independent
 - Probability that the ensemble classifier makes a wrong prediction:

$$\sum_{i=13}^{25} {25 \choose i} \varepsilon^i (1-\varepsilon)^{25-i} = 0.06$$

Examples of Ensemble Methods

Bagging

All classifiers are created equal

Boosting

Not all classifiers are created equal

Ensemble Methods

- Overview and rationale
- Binomial Distribution
- Bagging
- Random Forests
- Boosting
- AdaBoost

Bagging

Sampling with replacement

Original Data	1	2	3	4	5	6	7	8	9	10
Bagging (Round 1)	7	8	10	8	2	5	10	10	5	9
Bagging (Round 2)	1	4	9	1	2	3	2	7	3	2
Bagging (Round 3)	1	8	5	10	5	5	9	6	3	7

- Build classifier on each bootstrap sample
- For a training data of size n, each sample has probability $[1 (1 1/n)^n]$ of being selected
- If n is large, this approximates to 1-1/e ~ 0.632

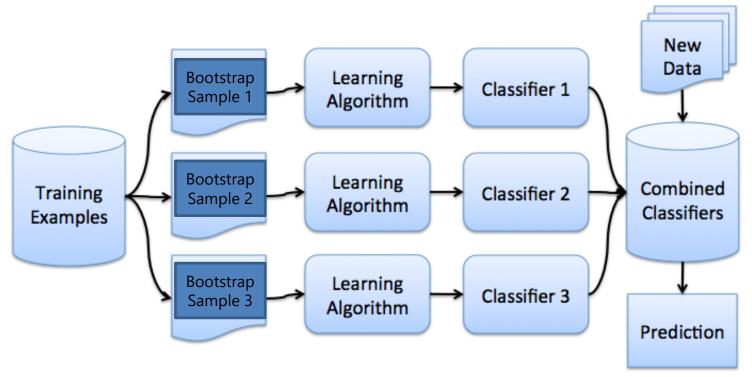

Bagging

- Reduces variance in estimate
- Prevents overfitting
- Robust to outliers

Bagging

Ensemble Methods

- Overview and rationale
- Binomial Distribution
- Bagging
- Random Forests
- Boosting
- AdaBoost

Random Forests Classifier

Random forests are a combination of tree predicators such that each tree depends on the values of a random vector sampled independently and with same distribution for all trees in the forest.

- Leo Breiman

What Is A Random Forest?

- An ensemble classifier using many decision tree models
- Can be used for classification or regression
- Accuracy and variable importance information is built-in

How Do Random Forests Work?

- A different subset of the training data are selected (~2/3), with replacement, to train each tree
- Remaining training data (aka out-of-bag data or simply OOB) is used to estimate error and variable importance
- Class assignment is made by the number of votes from all of the trees, and for regression, the average of the results is used

Which Features Are Used For Learning?

- A randomly selected subset of variables is used to split each node
- The number of variables used is decided by the user (mtry parameter in R)
- A smaller subset produces less correlation (lower error rate)

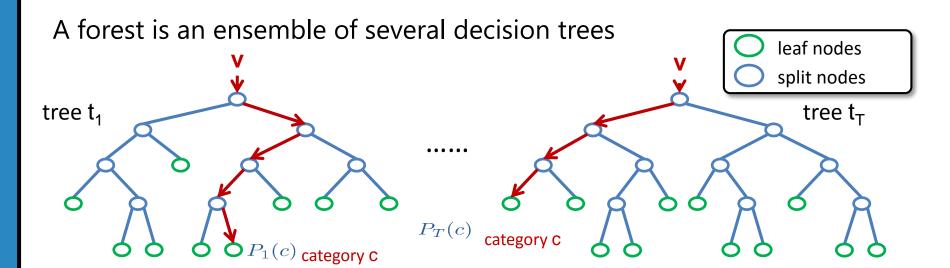

Rules of Thumb

- Given:
 - N: Total number of training data points
 - M: Number of features in training data
 - m: Number of features randomly selected for training each node

- Sample the data with replacement N times for building the training data for each tree.
- m < < M</p>
- Classification: m = sqrt(M)
- Regression: m = M/3

A Forest of Trees

Classification is
$$P(c|\mathbf{v}) = \frac{1}{T} \sum_{t=1}^{T} P_t(c|\mathbf{v})$$

[Amit & Geman 97] [Breiman 01] [Lepetit *et al.* 06]

Learning a Forest

- Dividing training examples into T subsets improves generalization
 - Reduces memory requirements & training time
- Train each decision tree t on subset I_t
 - Same decision tree learning as before
- Multi-core friendly (GPU implementation)

Implementation Details

- How many features and thresholds to try?
 - Just one = "extremely randomized" [Geurts *et al.* 06]
 - Few → fast training, may under-fit, may be too deep
 - Many → slower training, may over-fit
- When to stop growing the tree?
 - Maximum depth
 - Minimum entropy gain
 - Delta class distribution
 - Pruning

Ensemble Methods

- Overview and rationale
- Binomial Distribution
- Bagging
- Random Forests
- Boosting
- AdaBoost

Boosting

- An iterative procedure to adaptively change distribution of training data by focusing more on previously misclassified records
 - Initially, all N records are assigned equal weights
 - Unlike bagging, weights may change at the end of boosting round

Boosting

- Records that are wrongly classified will have their weights increased
- Records that are classified correctly will have their weights decreased

Original Data	1	2	3	4	5	6	7	8	9	10
Boosting (Round 1)	7	3	2	8	7	9	4	10	6	3
Boosting (Round 2)	5	4	9	4	2	5	1	7	4	2
Boosting (Round 3)	4	4	8	10	4	5	4	6	3	4

- Example 4 is hard to classify
- Its weight is increased, therefore it is more likely to be chosen again in subsequent rounds

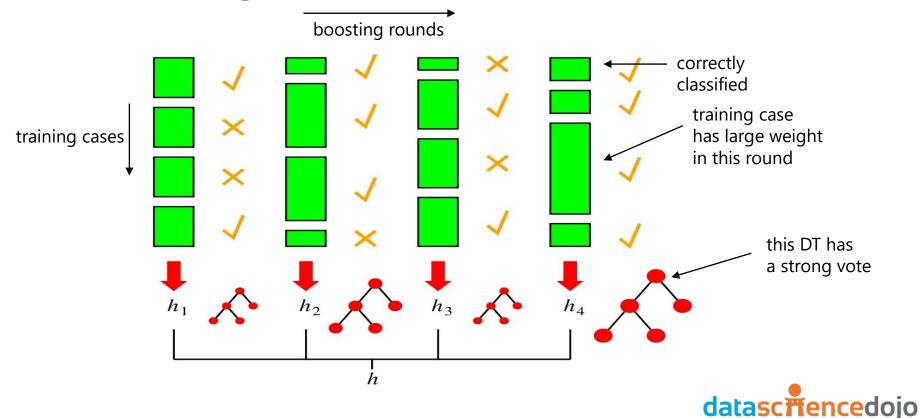

Boosting Intuition

- We adaptively weight each data case.
- Data cases which are wrongly classified get high weight (the algorithm will focus on them).
- Each boosting round learns a new (simple) classifier on the weighed dataset.
- These classifiers are weighed to combine them into a single powerful classifier.
- Classifiers that obtain low training error rate have high weight.
- We stop by monitoring a hold out set.

Boosting in a Picture

unleash the data scientist in you

Ensemble Methods

- Overview and rationale
- Binomial Distribution
- Bagging
- Random Forests
- Boosting
- AdaBoost

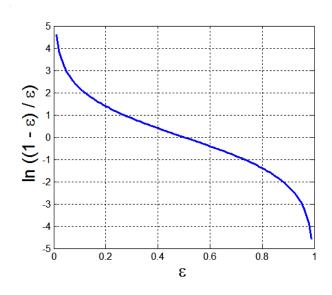

AdaBoost (Adaptive Boosting)

- Base classifiers: C₁, C₂, ..., C_T
- Error rate [Weighted loss function]:

$$\varepsilon_i = \frac{1}{N} \sum_{j=1}^{N} w_j \delta(C_i(x_j) \neq y_j)$$

Importance of a classifier:

$$\alpha_i = \frac{1}{2} \ln \left(\frac{1 - \varepsilon_i}{\varepsilon_i} \right)$$

AdaBoost

Weight update:

$$w_i^{(j+1)} = \frac{w_i^{(j)}}{Z_j} \begin{cases} \exp^{-\alpha_j} & \text{if } C_j(x_i) = y_i \\ \exp^{\alpha_j} & \text{if } C_j(x_i) \neq y_i \end{cases}$$

where Z_i is the normalization factor

- If any intermediate rounds produce error rate higher than 50%, the weights are reverted back to 1/n and the resampling procedure is repeated.
- Classification: $C*(x) = \arg\max_{y} \sum_{j=1}^{I} \alpha_{j} \delta(C_{j}(x) = y)$ datascriencedojo

Common Pitfall

A Random Forest and a Boosted Decision Tree are **not** the same
